British Mathematical Olympiad Solutions 1987 B

The British Mathematical Olympiad (BMO) is a prestigious competition designed to challenge the brightest young mathematicians in the UK. The 1987 BMO, particularly Part B, presented a series of intriguing problems that tested various areas of mathematical understanding, from algebra and number theory to combinatorics and geometry. In this comprehensive guide, we will explore the solutions to the 1987 BMO Part B problems, providing detailed explanations and strategies for each. This analysis aims to deepen understanding and serve as a valuable resource for students preparing for mathematical competitions.

Overview of the 1987 BMO Part B Problems

The BMO Part B typically comprises three challenging questions that require creative problem-solving and rigorous reasoning. The problems from 1987 B can be summarized as follows:

- Problem 1: An algebraic inequality involving positive real numbers.
- Problem 2: A number theory problem involving divisibility and prime factors.
- Problem 3: A combinatorial or geometric problem involving arrangements or constructions.

In the sections below, each problem will be discussed in detail, including the key ideas, step-by-step solutions, and common pitfalls.

Problem 1: Algebraic Inequality

Problem Statement

Given positive real numbers (a, b, c) such that $(a + b + c = 1)$, prove that:

$$\left[\frac{a}{b+c} + \frac{b}{a+c} + \frac{c}{a+b} \right] \geq \frac{3}{2}$$

Solution Approach

This problem is a classic inequality that can be approached through symmetry and the use of well-known inequalities like the Cauchy-Schwarz or the Rearrangement inequality. The key steps involve:

- Recognizing symmetry in the variables.
- Considering the equality case for motivation.
- Applying the substitution or inequality techniques to establish the bound.

Step-by-Step Solution

- **Symmetry and Intuition:** Since the inequality is symmetric in (a, b, c) , the minimum of the sum should occur at some symmetric point, often when all variables are equal, i.e., $(a = b = c)$.

- **Check the equality case:** If $(a = b = c = \frac{1}{3})$, then each term becomes:

$\left[$

$$\frac{\frac{1}{3}}{\frac{1}{3} + \frac{1}{3}} = \frac{\frac{1}{3}}{\frac{2}{3}} = \frac{1}{2}$$

$\left]$

Summing all three:

$\left[$

$$3 \times \frac{1}{2} = \frac{3}{2}$$

$\left]$

indicating that the inequality holds with equality at $(a = b = c = \frac{1}{3})$.

- **Applying the Cauchy-Schwarz Inequality:** To prove the inequality generally, consider the quantities:

$\left[$

$$S = \frac{a}{b+c} + \frac{b}{a+c} + \frac{c}{a+b}$$

$\left]$

and note that:

$\lfloor$

$$(b + c) = 1 - a, \quad (a + c) = 1 - b, \quad (a + b) = 1 - c$$

$\rfloor$

Therefore,

$\lfloor$

$$S = \frac{a}{1-a} + \frac{b}{1-b} + \frac{c}{1-c}$$

$\rfloor$

Since $(a, b, c) \in (0,1)$, the denominators are positive.

- Transform and bound the sum: Observe that:

$\lfloor$

$$\frac{a}{1-a} = \frac{a}{(1-a)} \geq 0$$

$\rfloor$

and the function $f(x) = \frac{x}{1-x}$ is increasing on $(0,1)$. Using Jensen's inequality with the convexity of f or comparing to the symmetric case, we can deduce the minimal sum occurs at the equal case, giving the bound of $\frac{3}{2}$.

Conclusion

The inequality holds with equality when $a = b = c = \frac{1}{3}$, confirming the conjecture. This problem exemplifies the elegance of symmetry and substitution in inequality proofs.

Problem 2: Number Theory

Problem Statement

Let p be a prime number greater than 3. Suppose that $(p^2 + 2)$ is divisible by $(p + 1)$. Show that $p \equiv 2 \pmod{3}$.

Solution Approach

This problem involves divisibility properties, modular arithmetic, and prime considerations. The key is to analyze the divisibility condition using polynomial division or modular congruences.

Step-by-Step Solution

- **Express the divisibility condition:** The problem states that:

[

$$p + 1 \mid p^2 + 2$$

]

meaning there exists an integer k such that:

[

$$p^2 + 2 = k(p + 1)$$

]

- **Rewrite the equation:** Expand the right side:

[

$$p^2 + 2 = kp + k$$

]

Rearranged as:

[

$$p^2 - kp + (2 - k) = 0$$

]

- **Consider the divisibility in modular form:** To analyze the divisibility, consider the congruence:

[

$$p^2 + 2 \equiv 0 \pmod{p + 1}$$

]

But note that:

[

$$p \equiv -1 \pmod{p + 1}$$

]

Therefore,

[

$$p^2 \equiv (-1)^2 = 1 \pmod{p + 1}$$

]

So,

[

$$p^2 + 2 \equiv 1 + 2 = 3 \pmod{p + 1}$$

]

For $(p + 1)$ to divide $(p^2 + 2)$, it must divide 3, hence:

[

$$p + 1 \mid 3$$

]

Since $(p + 1)$ divides 3, and (p) is a prime greater than 3, the possible values are:

[

$$p + 1 = 3 \implies p = 2$$

]

but this contradicts $(p > 3)$. Alternatively, check for divisibility by factors of 3:

- If $(p + 1 = 1)$, then $(p=0)$, not prime.
- If $(p + 1 = 3)$, then $(p=2)$, but $(p > 3)$, so discard.

Therefore, the previous deduction indicates that the divisibility condition holds only when $(p + 1)$ divides 3, which is only possible for $(p=2)$. Since $(p > 3)$, the initial modular approach suggests revisiting the problem.

- **Alternative approach:** Consider the original divisibility condition:

[

$$p + 1 \mid p^2 + 2$$

]

Perform polynomial division:

[

$$p^2 + 2 = (p + 1)(p - 1) + 3$$

]

since:

[

$$(p + 1)(p - 1) = p^2 - 1$$

]

Therefore,

[

$$p^2 + 2 = p^2 - 1 + 3 = (p + 1)(p - 1) + 3$$

$\backslash$

For $\backslash(p + 1 \backslash)$ to divide $\backslash(p^2 + 2 \backslash)$, it must divide the remainder 3:

$\backslash$

$$p + 1 \mid 3$$

$\backslash$

As before, only possible divisors are 1 and 3, leading to $\backslash(p + 1 = 3 \backslash)$ or 1, which yields $\backslash(p=2 \backslash)$ or $\backslash(p=0 \backslash)$, not satisfying the condition $\backslash(p > 3 \backslash)$.

Since the above leads to no solutions for $\backslash(p > 3 \backslash)$, the initial assumption must be checked for correctness.

Conclusion: The key insight is that the divisibility implies $\backslash(p + 1 \mid 3 \backslash)$, which is only possible when $\backslash(p=2 \backslash)$. But as $\backslash(p > 3 \backslash)$, the assumption leads to a contradiction unless the problem's conditions are interpreted differently.

British Mathematical Olympiad Solutions 1987 B: An In-Depth Analysis

The British Mathematical Olympiad (BMO) is a prestigious annual competition that challenges the brightest high school students across the United Kingdom. The 1987 BMO, particularly Part B, presented students with a series of intricate problems designed to test their problem-solving skills, logical reasoning, and mathematical creativity. This article offers a comprehensive review of the solutions to the 1987 BMO Part B, providing detailed explanations, analytical insights, and pedagogical reflections on each problem. Through this exploration, we aim to illuminate the depth and elegance of mathematical reasoning that underpins these challenging questions.

Overview of the 1987 BMO Part B

The 1987 BMO Part B consisted of five problems, each requiring sophisticated reasoning and a strong grasp of various mathematical concepts, including algebra, geometry, number theory, and combinatorics. Unlike Part A, which often features more straightforward computations, Part B emphasizes creative problem-solving and proof techniques.

The problems covered a diverse array of topics:

- Problem 1: An inequality involving positive real numbers.
- Problem 2: A geometric problem dealing with points and triangles.
- Problem 3: A number theory problem involving divisibility and prime factors.
- Problem 4: A combinatorial problem involving arrangements.
- Problem 5: An algebraic problem involving polynomial equations.

In this review, we will analyze each problem individually, providing detailed solutions, alternative approaches, and insights into the underlying mathematical principles.

Problem 1: An Inequality with Positive Real Numbers

Problem Statement:

Let (a, b, c) be positive real numbers such that $(abc = 1)$. Prove that:

[

$$a^2 + b^2 + c^2 \geq a + b + c.$$

]

Initial Observations and Symmetry

This problem is symmetric in (a, b, c) , which suggests that the extremal cases may occur when the variables are equal or when some tend to boundary values. The constraint $(abc = 1)$ links the variables multiplicatively, hinting at the use of inequalities like AM-GM or the substitution $(a = \frac{x}{y})$, $(b = \frac{y}{z})$, $(c = \frac{z}{x})$, which maintains the product.

Solution Approach 1: Applying AM-GM and Symmetry

Given $(abc = 1)$, by the AM-GM inequality:

[

$$a + b + c \geq 3 \sqrt[3]{abc} = 3.$$

]

However, this alone doesn't directly establish the desired inequality. Instead, consider the difference:

[

$$a^2 + b^2 + c^2 - (a + b + c) \geq 0,$$

]

which can be rewritten as:

[

$$(a - 1)^2 + (b - 1)^2 + (c - 1)^2 \geq 0,$$

]

but this is always true, yet it does not incorporate the condition $(abc=1)$.

Solution Approach 2: Symmetric Transformation

Suppose we set:

[

$$a = \frac{x}{y}, \quad b = \frac{y}{z}, \quad c = \frac{z}{x},$$

]

which satisfies $(abc = 1)$ automatically. Substituting into the inequality:

[

$$a^2 + b^2 + c^2 = \frac{x^2}{y^2} + \frac{y^2}{z^2} + \frac{z^2}{x^2},$$

]

and

[

$$a + b + c = \frac{x}{y} + \frac{y}{z} + \frac{z}{x}.$$

]

The inequality becomes:

$$\frac{x^2}{y^2} + \frac{y^2}{z^2} + \frac{z^2}{x^2} \geq \frac{x}{y} + \frac{y}{z} + \frac{z}{x}.$$

Multiplying through by $(y^2 z^2 x^2)$ (which is positive), we get:

$$x^2 z^2 x^2 + y^2 y^2 y^2 + z^2 x^2 z^2 \geq x y z (x z y + y x z + z y x),$$

which simplifies to a more complex expression. However, this approach tends to complicate matters, so perhaps direct application of inequalities is more straightforward.

Solution: Direct Application of Cauchy-Schwarz

Applying Cauchy-Schwarz inequality:

$$(a^2 + b^2 + c^2)(1 + 1 + 1) \geq (a + b + c)^2,$$

which simplifies to:

$$3(a^2 + b^2 + c^2) \geq (a + b + c)^2,$$

or equivalently,

$$\frac{a^2}{1} + \frac{b^2}{1} + \frac{c^2}{1} \geq \frac{(a+b+c)^2}{3}$$

$$a^2 + b^2 + c^2 \geq \frac{(a + b + c)^2}{3}.$$

\\

To prove the original inequality, it suffices to show:

\\

$$a + b + c \leq 3,$$

\\

given $(a, b, c > 0)$ and $(abc = 1)$.

From AM-GM:

\\

$$a + b + c \geq 3 \sqrt[3]{abc} = 3,$$

\\

so the minimum of $(a + b + c)$ is 3, which occurs when $(a = b = c = 1)$. Substituting $(a = b = c = 1)$:

\\

$$a^2 + b^2 + c^2 = 3,$$

\\

and

\\

$$a + b + c = 3,$$

\\

so equality holds, satisfying the inequality.

Thus, the inequality is minimized at $(a = b = c = 1)$, and for all positive (a, b, c) with $(abc = 1)$, the inequality holds.

Conclusion for Problem 1

The key insight lies in recognizing the symmetry and applying classical inequalities like AM-GM and Cauchy-Schwarz. The equality case at $(a = b = c = 1)$ confirms the tightness of the inequality, illustrating the elegance of symmetrical inequalities under multiplicative constraints in algebra.

Problem 2: Geometric Configuration and Area Inequalities

Problem Statement:

In triangle (ABC) , points (P) and (Q) lie on sides (AB) and (AC) respectively. The lines (PQ) and (BC) intersect at (R) . Prove that:

$$\text{Area}(APQ) \leq \text{Area}(ABC) \times \frac{AP}{AB} \times \frac{AQ}{AC}.$$

Understanding the Geometric Setup

This problem involves ratios of segments and areas within a triangle, which suggests the use of similar triangles, ratios, and perhaps the concept of affine transformations. The key is to relate the areas of the smaller triangle (APQ) to the original (ABC) .

Solution Approach: Using Similarity and Ratios

Let's denote:

- $(AP = p)$, with $(0 < p < AB)$
- $(AQ = q)$, with $(0 < q < AC)$

Since (P) lies on (AB) , the point (P) divides (AB) into segments $(AP = p)$ and $(PB = AB - p)$. Similarly, (Q) divides (AC) .

The area of (APQ) can be expressed in terms of ratios:

$$\frac{\text{Area}(APQ)}{\text{Area}(ABC)} = \frac{AP}{AB} \times \frac{AQ}{AC},$$

$$\frac{\text{Area}(APQ)}{\text{Area}(ABC)} = \frac{AP}{AB} \times \frac{AQ}{AC},$$

$$\frac{\text{Area}(APQ)}{\text{Area}(ABC)} = \frac{AP}{AB} \times \frac{AQ}{AC},$$

if (P) and (Q) are chosen such that (P) and (Q) are proportional along (AB) and (AC) , respectively, and the line (PQ) intersects (BC) at (R) .

Formal Proof via Affine Transformation

Because affine transformations preserve ratios of areas, we can normalize the triangle (ABC) to a convenient coordinate system—for example, position:

- $(A = (0, 0))$,
- $(B = (b, 0))$,
- $(C = (0, c))$.

In this coordinate system:

- (P) lies on (AB) , so $(P = (t b, 0))$, where $(0$
- (Q) lies on (AC) , so $(Q = (0, s c))$, where $(0$

The area of the original triangle:

$$\text{Area}(ABC) = \frac{1}{2} b c.$$

$$\text{Area}(ABC) = \frac{1}{2} b c.$$

$$\text{Area}(APQ) = \frac{1}{2} t s b c.$$

The area of (APQ) :

$$\text{Area}(APQ) = \frac{1}{2} t s b c.$$

$$\text{Area}(APQ) = \frac{1}{2} t s b c.$$

math olympiad questions and answers 2013

Exploring Math Olympiad Questions and Answers 2013: A Comprehensive Guide

math olympiad questions and answers 2013 continue to serve as a valuable resource for students and educators aiming to enhance problem-solving skills and mathematical understanding. The 2013 Olympiad papers featured a variety of challenging problems that tested candidates' logical reasoning, analytical skills, and mathematical creativity. In this guide, we delve into some of the most notable questions from the 2013 Olympiad, providing detailed solutions and strategies to approach similar problems.

Overview of the 2013 Math Olympiad

The 2013 Math Olympiad was an international event that attracted talented students from numerous countries. The exam typically comprises multiple-choice and descriptive questions, covering topics such as algebra, geometry, number theory, combinatorics, and probability. The questions are designed to challenge students beyond routine calculations and encourage innovative thinking.

The 2013 edition included problems that ranged from straightforward to highly complex, often requiring multiple steps and clever insights. Understanding these problems and their solutions can significantly improve one's problem-solving prowess and prepare students for future Olympiads.

Notable Questions from the 2013 Olympiad

Below are some highlighted questions from the 2013 Olympiad, along with detailed explanations:

Question 1: A Number Theory Challenge

Problem:

Find all positive integers n such that $n^2 + 5n + 6$ is a perfect square.

Solution Strategy:

- Recognize that the quadratic can be factored or rewritten.
- Set $n^2 + 5n + 6 = k^2$, where k is an integer.
- Rewrite as $n^2 + 5n + 6 - k^2 = 0$.

Step-by-step Solution:

- Rewrite the equation:

$$n^2 + 5n + (6 - k^2) = 0.$$

- Consider n as a variable and treat the equation as quadratic in n :

$$n^2 + 5n + (6 - k^2) = 0.$$

- For integer solutions in n , the discriminant D must be a perfect square:

$$D = 25 - 4(6 - k^2) = 25 - 24 + 4k^2 = 1 + 4k^2.$$

- Set $D = t^2$ for some integer t :

$$t^2 = 1 + 4k^2.$$

- Rearranged as:

$$(t^2 - 4k^2 = 1).$$

- Recognize this as a difference of squares:

$$(t - 2k)(t + 2k) = 1).$$

- Since t and k are integers, the only integer solutions occur when:
 - $t - 2k = 1$ and $t + 2k = 1$, which implies $t = 1$ and $k = 0$.
 - Or $t - 2k = -1$ and $t + 2k = -1$, which implies $t = -1$ and $k = 0$.

Conclusion:

- When $k = 0$, substitute back into the quadratic for n :

$$(n^2 + 5n + 6 = 0).$$

- Solve:

$$(n = \frac{-5 \pm \sqrt{25 - 24}}{2} = \frac{-5 \pm 1}{2}).$$

- Therefore, $n = \frac{-5 + 1}{2} = -2$ or $n = \frac{-5 - 1}{2} = -3$.
- Since n must be positive, discard negative solutions.

Answer:

No positive integer solutions satisfy the condition.

Question 2: Geometry Problem on Triangles

Problem:

In triangle ABC , point D lies on side BC . The lines AD , BE , and CF are concurrent, where E and F are points on sides CA and AB respectively. If AD is the median, prove that the three cevians are concurrent at a point inside the triangle.

Solution Strategy:

- Use Ceva's Theorem and properties of medians.
- Show that the given cevians satisfy the conditions for concurrency.

Key Steps:

- Since AD is the median, D is the midpoint of BC .
- For lines BE and CF to be concurrent with AD , they must satisfy Ceva's theorem:

$$\frac{AF}{FB} \times \frac{BD}{DC} \times \frac{CE}{EA} = 1.$$

- Given D is midpoint, $BD = DC$, so $\frac{BD}{DC} = 1$.
- To establish the concurrency, choose appropriate ratios for $AF:FB$ and $CE:EA$.
- Under the right ratios, by Ceva's theorem, the three cevians intersect at a common point.

Conclusion:

Using properties of medians and Ceva's theorem, the three cevians AD , BE , and CF are indeed concurrent, forming the centroid or another point depending on the ratios.

Overview of Math Olympiad 2013

The 2013 Olympiad problems spanned a diverse array of topics, including algebra, geometry, number theory, and combinatorics. They were designed to test not just computational skills but also ingenuity, logical deduction, and the ability to approach problems from multiple angles.

The questions typically ranged from relatively straightforward to highly challenging, often requiring creative insights or novel approaches. The answers provided detailed solutions, emphasizing the importance of clear reasoning and the elegance of mathematical solutions.

Dissecting the 2013 Olympiad Questions

Geometry Problems

Geometry questions are a staple of math olympiads, emphasizing spatial reasoning and the application of classic theorems.

Sample Problem:

Given a triangle ABC with points D , E , and F on sides BC , AC , and AB respectively, such that DE , EF , and FD are concurrent. Prove that the cevians AD , BE , and CF are also concurrent.

Analysis and Solution:

- Key Concepts: Ceva's Theorem, concurrency, ratios along sides.
- Approach:

- Recognize that the problem involves cevians and their concurrency properties.
- Use Ceva's Theorem to relate the ratios in which the points divide the sides.
- Show that the concurrency of the three lines AD, BE, and CF follows from the given conditions using ratios.

Step-by-step reasoning:

- Assign variables to side segments to express ratios.
- Apply Ceva's Theorem to the triangle ABC with the cevians.
- Use the given points D, E, F and the fact that DE, EF, and FD are concurrent to establish ratios.
- Demonstrate that the ratios satisfy Ceva's Theorem for the cevians AD, BE, CF, hence proving their concurrency.

Mathematical beauty: The problem elegantly ties together properties of cevians and ratios, illustrating the interconnectedness of geometric concepts.

Number Theory Problems

Number theory questions in 2013 tested properties of integers, divisibility, and prime factorization.

Sample Problem:

Find all integers $n > 1$ such that $n^2 + 2n + 1$ is divisible by $n + 1$.

Analysis and Solution:

- Key insight: Recognize that $n^2 + 2n + 1$ factors as $(n + 1)^2$.
- Solution:
- Rewrite the divisibility condition as $(n + 1)^2$ divisible by $n + 1$.
- Since $(n + 1)$ divides itself, this is always true.
- For $n > 1$, $n + 1 > 2$, so the divisibility always holds.

Answer:

- All integers $n > 1$ satisfy the condition.

This problem exemplifies how recognizing algebraic identities simplifies seemingly complex divisibility questions.

Algebra and Functional Equations

Algebraic manipulation and functional equation solving are core skills tested.

Sample Problem:

Find all functions $f: \mathbb{R} \rightarrow \mathbb{R}$ such that for all real numbers x and y :

$$f(x + y) = f(x) + f(y) + xy.$$

Analysis and Solution:

- Key ideas: Functional equations, substitution, symmetry.
- Step-by-step:
 - Set $y = 0$ to find $f(x + 0) = f(x) + f(0) + 0$, which implies $f(x) = f(x) + f(0)$, so $f(0) = 0$.
 - Explore the form of f by trying to express it as a polynomial.
 - Assume $f(x) = ax^2 + bx + c$; since $f(0) = 0$, $c = 0$.
 - Plug into the original equation:
 - $a(x + y)^2 + b(x + y) = ax^2 + bx + ay^2 + by + xy$.
 - Expand and compare coefficients:
 - $ax^2 + 2axy + ay^2 + bx + by = ax^2 + bx + ay^2 + by + xy$.
 - Equate terms:
 - $2a xy = xy \Rightarrow 2a = 1 \Rightarrow a = 1/2$.
 - Conclusion:

$f(x) = (1/2)x^2 + bx$, where b is any real constant.

Final answer:

$f(x) = (1/2)x^2 + bx$, for arbitrary real b .

Combinatorics and Counting Problems

Counting problems often involve clever enumeration, inclusion-exclusion, or symmetry.

Sample Problem:

In a class of 30 students, 18 like mathematics, 12 like physics, and 8 like both. How many students like at least one of these two subjects?

Solution:

- Use the inclusion-exclusion principle:
- Total students who like mathematics or physics = (number who like math) + (number who like physics) - (number who like both).
- So, $18 + 12 - 8 = 22$.

Answer:

22 students like at least one of the two subjects.

This problem demonstrates the power of basic combinatorial principles applied thoughtfully.

Common Strategies for Olympiad Problems

To excel in math olympiads like those in 2013, students often rely on a set of proven strategies:

- Identify the Core Concept: Recognize whether the problem is algebraic, geometric, number-theoretic, or combinatorial.
- Simplify the Problem: Look for substitutions, factorizations, or symmetry to reduce complexity.
- Use Known Theorems: Ceva, Menelaus, Pythagoras, Fermat's Little Theorem, etc.
- Work Backwards: Think about the desired result and consider what conditions lead there.
- Check Special Cases: Test small or particular values to gain insight.
- Draw Diagrams: Visual representations often reveal hidden relationships.
